

## ABSTRACT OF THE DISCLOSURE

System, methods, and apparatus for verifying microcircuit designs by interleaving between random and formal simulation techniques to identify input traces useful for driving DUTs into sequences of device states. In a method aspect the invention provides

5 process for beginning random simulation of a sequence of states of a microcircuit design by inputting a sequence of random input vectors to a DUT model in order to obtain a sequence of random simulation states; monitoring a simulation coverage progress metric to determine a preference for switching from random simulation to formal methods of

10 simulating states in the DUT; beginning formal simulation of states in the DUT and monitoring a formal coverage progress metric to determine a preference for resuming random simulation of states of said microcircuit design; and resuming random simulation. Preferably the process of interleaving simulation methods continues until an input vector suitable for driving the DUT model into each of a set of previously-identified goal states has been obtained.
